

It never takes a position it can't cover.

An autonomous options agent on Alpaca. Every structure's maximum loss is computed and set aside **before** the order is submitted.

Most trading agents can tell you what they bought.

Very few can tell you what it costs them if it goes against them — **before** they buy it.

Give an autonomous agent a brokerage account and it will place trades. That part is solved. The unanswered question is what happens when it is wrong.

The flat floors are the claim.

keeps the credit while price stays between the short strikes — **\$3,727** collected

loss cannot deepen past the floor — **\$26,573** reserved

An iron condor is four legs, which is exactly Alpaca's **4-legs** limit. Only one side can ever be breached, so the maximum loss is width minus credit — known before the order exists.

The proof and the order are the same request.

```
alpaca order submit --order-class mleg --qty 5
--type limit --limit-price 0.53
--client-order-id vig-3f9a1c22
--legs [ 4 legs ]      --dry-run  ← renders it
--legs [ 4 legs ]      ← then sends it
```

Execution runs entirely through the Alpaca CLI. Every order is submitted twice: once rendered without sending, then again as the identical command. Each structure carries its receipt, and the receipt is the command.

Eight gates. Every one can say no.

01	illiquid	any leg's bid/ask wider than \$0.15
02	thin-credit	credit under 10% of width
03	position-too-large	one structure risking more than 5% of equity
04	bucket-full	one underlying and expiry past 6% of equity
05	book-full	total reserved past the 25% ceiling
06	no-wing	the protective strike does not exist
07	inverted	short strikes crossed; loss no longer bounded
08	regime	the newswire says today is a bad day to be short premium

They match because they have to. Live on a paper account across SPY, QQQ and IWM — every figure read through the Alpaca CLI, none of it mocked.

THE RESULT

06

What this does not claim.

Paper trading, and roughly two and a half sessions of it. That is not a sample size from which an edge can be inferred, and none is claimed. Selling premium wins often and loses occasionally larger; that skew is real, and the ceilings bound what it can cost rather than pretending it away.

What is checkable is narrower. Every position is covered before it exists.
